~~SPECIAL HANDLING - SECRET~~

1.0 SCOPE

The Resolution tests were performed to determine the optical properties of the Slide Viewing System (SVS) as a function of magnification, field position, contrast, and anamorphism. Comparisons of these properties were made between the resolution at the dummy reticle and the resolution at the eyepiece using the interim eyepiece. A telescope will be used with the eyepiece to establish data that will not be "eye-limited". The results will be published as an addendum to this report. This report is an interim report and covers only the resolution testing following review and customer direction for additional testing. Results of all previous testing were reported in Itek-Customer meetings.

2.0 APPLICABLE DOCUMENTS

The Applicable Documents include:

2.1 SDR 154-2

2.2 TR 1429 A

2.3 SDR 151-8

2.4 344-68-063

2.5 344-68-063/B Add 1

3.0 TEST DESCRIPTION

Figure 1, of the test plan document number 344-68-063/B addendum 1, shows the test configuration. The Optical System was examined over the following field of Optical parameters listed below:

Step Magnification—High and Low.

Zoom Ratio—Low/Medium/High

Anamorph Ratio—1.1, 2.1, none

Field Position—(0, 0)
(X at + 0.5, + 1.0)
(Y at + 0.5, + 1.0)

Target Contrast—1.6 to 1 (Negative only)
6 to 1 (Negative only)

Color—White Light only

Positions—With the Eyepiece
At the dummy retical

One hundred and twenty six data points were examined and the results of these readings is shown in Section 4.0 of this report.

Other Specifications and test criteria included.

a. All readings were made in H/V (horizontal/vertical).

b. Ophthalmic tests were made on each observer and the results can be found in Section 5.1 of this report. These tests were specified in SDR-151-8.

c. While the bench did not always include elements to represent the new beamsplitter and the intensity modulator, these were placed into the system towards the completion of the testing phase and at that time no degradation of resolution occurred either on axis or at the off-axis positions.

d. Two observers were used to record the data, with two other observers used for backup only.

→ e. All the testing was with the 4mm final exit pupil.

f. Readings for axial settings were optimized by centering the target and pointer with the microscope so that the limiting resolution group was near the optical axis, as was specified in SDR-151-8. *WHAT ABOUT OFF AXIS READINGS?*

4.0 TEST RESULTS

4.1 Resolution as a Function of Contrast

The following table relates resolution as a function of contrast. All the data was collected during the qualitative test with the exception of additional data using a 1000:1 contrast target.

The data in the table was taken using the interim eyepiece.

Table 1

Mag.			1000:1*		6:1		1.6:1	
			on axis	Full-X	On axis	Full-X	On axis	Full-X
25.7	↑ High step- MAG ↓	H	228/203	203/181	153/144	136/144	128/128	
13.6		M	128/128	114/102	87/92	-----	72/72	-----
3.6		L	29/32	29/25	23/26	21/17	-----	-----
36.4/18.2		H	144/144	-----	114/114	121/161	82/92	-----
19.2/9.6		M	81/102	-----	61/64	-----	48/61	-----

~~SPECIAL HANDLING SECRET~~

Resolution as a function of contrast is plotted below (Fig. 1 and Fig. 2) for field Magnification, on axis, 1:1 Anamorphism only, and for both the reticle and eyepiece location. The eye limit defined as 7 l/mm for 1 X is given at 30X as $30(7) = 210$ l/mm and shown on each chart for reference. A slight fall off in resolutions at the edge of the field does occur but is not contrast dependent. Therefore, no comparison of the resolution in the field as a function of contrast has been made.

An analysis was performed showing critical areas of astigmatic differences between the horizontal and vertical readings. Some of these were individual differences and have been eliminated from the following chart. (see Table 2) As shown on the chart most of these differences are due to positioning the target off axis in the field. The on axis readings at 1.6 to one are a direct effect of the low contrast target. Possible explanations for this effect include:

→ a. A defect of the target, as would occur in the processing of the target or, an effect of low contrast targets on the visual process.

b. It should be noted here that the effect of the Anamorphs in producing any astigmatic difference is negligible and not substantiated by the data summarized in Table 2. It does not appear to produce any more astigmatism at 2:1 than 1:1.

→ WHICH IS THIS TABLE?

4.2 The Anamorphs and Resolution

The remaining resolution vrs, magnification data are given below. Only the 6:1 contrast data is shown. For the 1.6:1 data refer to the test matrix in the appendix of this report. Comments on the result of each chart are given below.

Fig. 3 Anamorphs 1:1 on axis.

Fig. 4 Anamorphs 1:1 Full "X" field.

The term full "X" field refers to the 1.0X on the test Matrix. The resolution drops slightly but not critically at the edge of the field. The increased resolution in the high power at the dummy reticle is believed to be due to the fact that the observers were looking at a vignetted image and the edge effects, enhanced the resolution reading.

Fig. 5 Anamorphs 1:1 full "Y" field. The full "Y" field refers to the 1.0 Y on the test matrix. The curve is similar to the full "X" field without the error at the edge of the field as mentioned above.

Fig. 6 Without Anamorphs on axis. There is little change here from the on axis condition with the Anamorphs at 1:1.

(2) THE THREE (3) BASIC ZOOM-LENS FOCAL LENGTH SETTINGS CORRESPOND TO MINIMUM MAGNIFICATION (L), MAXIMUM MAGNIFICATION WHEN RETROFIT ZOOM EYEPIECE IS USED (M), & MAXIMUM MAGNIFICATION WHEN INTERIM EYEPIECE IS USED (H). SPECIFIC FOCAL LENGTH VALUES ARE TO BE CALIBRATED.

(3) READINGS ARE RECORDED: HORIZONTAL BAR/VERTICAL BAR.

SPECIAL HANDLING ~~SECRET~~

Fig. 7 Without Anamorphs, Full X field. In comparison with the full "X" field and anamorphs at 1:1, the resolution is reduced by taking the anamorphs out of the system, (at the full X field and dummy reticle position). At the eyepiece however the resolution is slightly enhanced.

Fig. 8 Without Anamorphs, full Y field. The resolution is reduced by taking the anamorph out of the system at the full Y field at the dummy reticle for high power. At low power relay it is about the same and in some places slightly higher with the anamorph out of the system. No readings were made at the eyepiece.

Fig. 9 Anamorphs 2.1 on axis. At the dummy reticle the resolution is greatly reduced in the horizontal direction, while in the vertical direction the resolution is approximately the same as the 1:1 condition axis or the no anamorph condition on axis.

Fig. 10 Anamorphs 2.1 on axis at the eyepiece. The reduction in resolution from the other on axis curves is in the horizontal direction while in the vertical direction the resolution is the same.

Fig. 11 Anamorph 2.1, Full X position. (a) the Horizontal resolution for both the eyepiece and dummy reticle is greatly reduced. (b) The vertical resolution for both the eyepiece and dummy reticle is greatly enhanced.

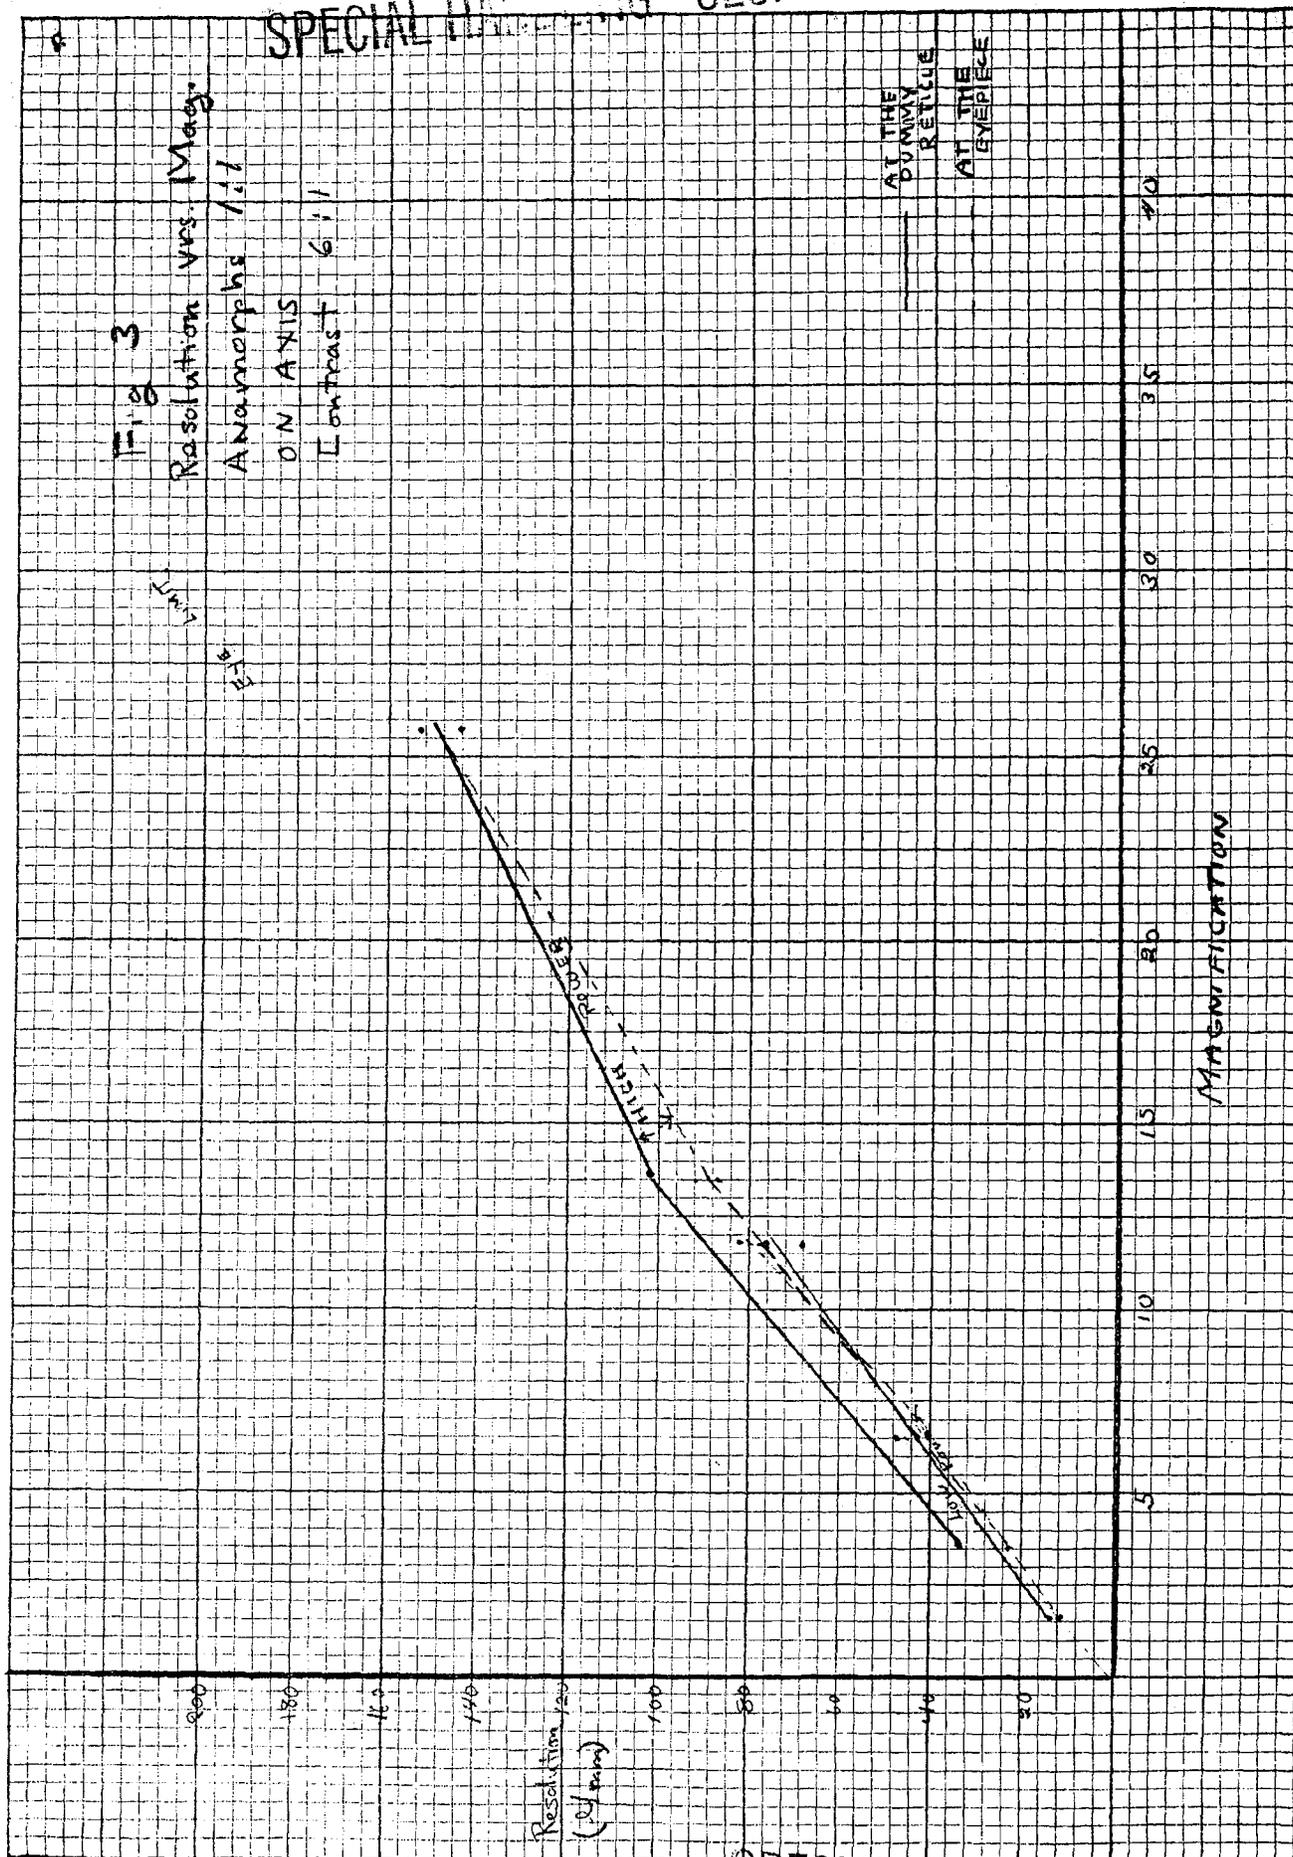

Fig. 12 Anamorph 2.1 Full Y Position. The horizontal resolution both at the dummy reticle and at the eyepiece is reduced while for the vertical it is enhanced.

4.3 Magnification and Resolution

Table 3 below shows the resolution difference between the dummy reticle position and the eyepiece for various magnifications. The magnification is changed by the anamorphs as shown in the previous data (Figures 9 through 12). Resolution is also reduced by the magnification fall off across the field. This is only a small sampling of the data but is sufficient to show general tendencies.

Table 3 — Magnification and Resolution

Parameters: 6:1 Contrast Anamorphs 1:1 Average Resolutions on Axis

Magnification	At Reticle	At Eyepiece
	(Horizontal/Vertical) Res. (1/mm)	(Horizontal/Vertical) Res. (1/mm)
1.6	14/14	12/12
3.6	34/34	23/26
6.4	48/48	41/46
11.7	77/68	77/82
13.6	102/102	87/92
25.7	153/144	153/144

4.4 Resolution Across the Field (X Direction)

The following generalizations can be made concerning the X field.

- a. Without the anamorphs in the system, there is no set pattern of fall off across the field. At some of the points it has obviously decreased in resolution while at others it has increased in 0.5x position and decreased at the 1.0x position.
- b. Placing the anamorphs in the system at 1:1 increases the resolution across the field for 1.0 X and 1.0 Y.
- c. With the anamorphs at 2:1 the resolution on axis and at 1.0x and 1.0 y for the horizontal bars is reduced from the 1:1 anamorphic condition. The vertical bar resolution is increased.

4.5 Resolution Across the Field (Y Direction)

The same comments as in Section 4.4 of this report apply to the Y direction.

END OF TEXT

SPECIAL HANDLING - ~~SECRET~~

SPECIAL HANDLING -~~SECRET~~

4.6 Comparison of the Resolution at the Dummy Reticle Position
and at the Eyepiece

The following generalizations can be made:

- a. The resolution at the reticle is slightly higher than at the eyepiece.
- b. For field positions the dropoff of resolution is consistent for the reticle and the eyepiece.
- c. Contrast reduction effects the resolution at the dummy reticle more than at the eyepiece.
- d. When the anamorphs are taken out of the system the "X" resolution at the reticle drops while at the eyepiece the resolution rises slightly. In the Y direction the same dropoff occurs at the reticle but the eyepiece resolution slightly decreases.
- e. At both the eyepiece and reticle the resolution in the vertical remains the same on axis when the anamorphs are set at 2:1. Under the same conditions the horizontal resolution at both reticle and eyepiece deteriorates.
- f. At off axis conditions with the anamorphs at 2:1 the difference between the reticle resolution and the eyepiece resolutions are minor compared with the enhancement of vertical resolutions and the reduction of horizontal resolution brought about by the anamorphs.

CARRY OVER

5.3 Summary

The resolution varies as a function of magnification, field position, contrast, and anamorphism. It increases with increased magnification, increased contrast, and positive anamorphism. Even though these generalizations could easily have been predicted, the exact amount of resolution degradation was not known nor was the effect of eye limitation on the system operator performance.

Further experiments will be conducted on the interim eyepiece data to reduce the eye limitations using a telescope to view the eyepiece image. This will be published as an addendum to the report and will compare these results with the present findings.

Prior to taking the data reported here, the bench was moved and realigned using a "pinhole" method. This created a better quality image with much less color and reduced flare. The resolution does not differ from all previous testing at the dummy reticle.

→ The eyepiece data can not be compared until the tests with the telescope (as mentioned above) are complete.

NOTES: (1) MEASUREMENTS WILL BE REPEATED AT THREE (3) RADIAL FIELD POSITIONS (H), AXIAL (O), 50% ZONE (O.5), & FULL FIELD (O), X HORIZONTAL TO RIGHT, Y VERTICAL UP.

(2) THE THREE (3) BASIC ZOOM LENGTH SETTINGS CORRESPOND TO MINIMUM MAGNIFICATION (L), MAXIMUM MAGNIFICATION WHEN RETROFIT ZOOM EYEPIECE IS USED (M), & MAXIMUM MAGNIFICATION WHEN INTERIM EYEPIECE IS USED (H). SPECIFIC FOCAL LENGTH VALUES ARE TO BE CALIBRATED.

(3) READINGS ARE RECORDED: HORIZONTAL BAR/VERTICAL BAR.
